AVL Trees

Reading: *Chap. 4, Weiss*

# *Sorting with BST*

---

- ✚ Use binary search trees for sorting
- ✚ Start with unsorted sequence
- ✚ Insert all elements in a BST
- ✚ Traverse the tree.... how ?
- ✚ Running time?

# *Better Binary Search Trees*

---

Prevent the degeneration of the BST :

- ✚ A BST can be set up to maintain balance during updating operations (insertions and removals)
- ✚ Types of BST which maintain the optimal performance:
  - ✚ splay trees
  - ✚ [AVL trees](#)
  - ✚ Red-Black trees
  - ✚ B-trees

# AVL Trees

- ✚ Balanced binary search trees
- ✚ An AVL Tree is a *binary search tree* such that for every internal node  $v$  of  $T$ , the **heights of the children of  $v$  can differ by at most 1**.

# Height of an AVL Tree

- ✚ **Proposition:** The **height** of an AVL tree  $T$  storing  $n$  keys is  $O(\log n)$ .
- ✚ **Justification:** The easiest way to approach this problem is to find  **$n(h)$** : the *minimum number of nodes* of an AVL tree of height  $h$ .
- ✚  $n(1) = 2$  and  $n(2) = 4$
- ✚ for  $n \geq 3$ , an AVL tree of height  $h$  contains the root node, one AVL subtree of height  $h-1$  and the other AVL subtree of height  $h-2$ .
- ✚  $\square \quad n(h) = 1 + n(h-1) + n(h-2)$
- ✚ given  $n(h-1) > n(h-2) \quad \square \quad n(h) > 2n(h-2)$ 
  - $n(h) > 2n(h-2)$
  - $n(h) > 4n(h-4)$
  - ...
  - $n(h) > 2^i n(h-2i)$
- ✚ pick  $i = h/2 - 1 \quad \square \quad n(h) \geq 2^{h/2-1}$
- ✚ follow  $h < 2 \log n(h) + 2$
- ✚  $\square$  height of an AVL tree is  $O(\log n)$

# Insertion

---

- ✚ A binary search tree  $T$  is **balanced** if for every node  $v$ , the height of  $v$ 's children differ by at most one.
- ✚ Inserting a node into an AVL tree involves performing a **expandExternal( $w$ )** on  $T$ , which changes the heights of the nodes in  $T$ .
- ✚ If an insertion causes  $T$  to become **unbalanced**, we traverse the tree from the newly created node until we find the first node  $z$  such that its grandparent  $z$  is an unbalanced node.
- ✚ Since  $z$  became unbalanced by an insertion in the subtree at its child  $y$ ,  $\text{height}(y) = \text{height}(\text{sibling}(y)) + 2$
- ✚ Need to rebalance...

## *Insertion: Rebalancing*

---

- ✚ To rebalance the subtree rooted at  $z$ , we must perform a **restructuring**
- ✚ we rename  $x$ ,  $y$ , and  $z$  to  $a$ ,  $b$ , and  $c$  based on the order of the nodes in an in-order traversal.
- ✚  $z$  is replaced by  $b$ , whose children are now  $a$  and  $c$  whose children, in turn, consist of the four other subtrees formerly children of  $x$ ,  $y$ , and  $z$ .

# Insertion (cont'd)

unbalanced...

...balanced

# Restructuring

- ✚ The four ways to rotate nodes in an AVL tree, graphically represented
- Single Rotations:

# Restructuring (cont'd)

double rotations:

# Restructure Algorithm

---

## Algorithm **restructure**(**x**):

Input: A node  $x$  of a binary search tree  $T$  that has both a parent  $y$  and a grandparent  $z$

Output: Tree  $T$  restructured by a rotation (either single or double) involving nodes  $x$ ,  $y$ , and  $z$ .

- 1: Let  $(a, b, c)$  be an inorder listing of the nodes  $x$ ,  $y$ , and  $z$ , and let  $(T_0, T_1, T_2, T_3)$  be an inorder listing of the the four subtrees of  $x$ ,  $y$ , and  $z$ , rooted at  $x$ ,  $y$ , or  $z$ .
2. Replace the subtree rooted at  $z$  with a new subtree rooted at  $b$
3. Let  $a$  be the left child of  $b$  and let  $T_0, T_1$  be the left and right subtrees of  $a$ , respectively.
4. Let  $c$  be the right child of  $b$  and let  $T_2, T_3$  be the left and right subtrees of  $c$ , respectively.

# Cut/Link Restructure Algorithm

- Let's go into a little more detail on this algorithm...
- Any tree that needs to be balanced can be grouped into 7 parts: x, y, z, and the 4 trees anchored at the children of those nodes ( $T_0, T_1, T_2, T_3$ )

# Cut/Link Restructure Algorithm

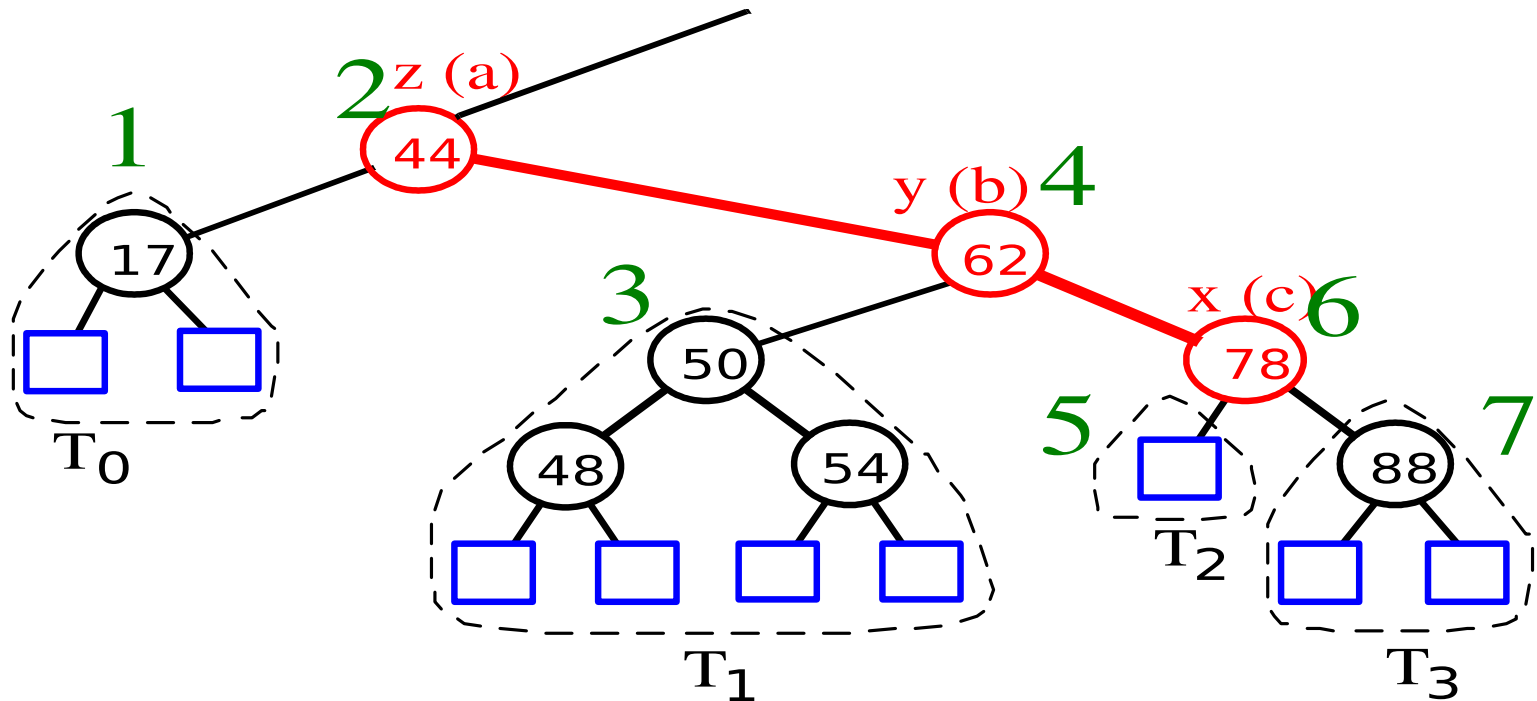

- Make a new tree which is balanced and put the 7 parts from the old tree into the new tree so that the numbering is still correct when we do an in-order-traversal of the new tree.
- This works regardless of how the tree is originally unbalanced.
- Let's see how it works!

# Cut/Link Restructure Algorithm

- Number the 7 parts by doing an in-order-traversal. (note that x,y, and z are now renamed based upon their order within the traversal)

# Cut/Link Restructure Algorithm

- Now create an Array, numbered 1 to 7 (the 0th element can be ignored with minimal waste of space)

- Cut() the 4 T trees and place them in their inorder rank i

# Cut/Link Restructure Algorithm

- Now cut x, y, and z in that order (child, parent, grandparent) and place them in their inorder rank in the array.

- Now we can re-link these subtrees to the main tree.
- Link in rank 4 (b) where the subtree's root formerly

# Cut/Link Restructure Algorithm

Link in ranks 2 (a) and 6 (c) as 4's children.

# Cut/Link Restructure Algorithm

- Finally, link in ranks 1, 3, 5, and 7 as the children of 2 and 6.

- Now you have a balanced tree!

# *Cut/Link Restructure Algorithm*

---

- ✚ This algorithm for restructuring has the exact same effect as using the four rotation cases discussed earlier.
- ✚ Advantages: no case analysis, more elegant
- ✚ Disadvantage: can be more code to write
- ✚ Same time complexity

# Removal

---

- ✚ We can easily see that performing a **removeAboveExternal**(w) can cause T to become unbalanced.
- ✚ Let **z** be the **first unbalanced** node encountered while traveling up the tree from w. Also, let y be the child of z with the larger height, and let x be the child of y with the larger height.
- ✚ We can perform operation **restructure**(x) to restore balance at the subtree rooted at z.
- ✚ As this restructuring may upset the balance of another node higher in the tree, we must continue checking for balance until the root of T is reached

# Removal (cont'd)

example of deletion from an AVL tree:

# Removal (cont'd)
