Graphs: Traversals and Shortest Path Algorithms (Chapter 9)

CSE 373

Data Structures and Algorithms

5/21/10

Today's Outline

- Announcements
 - Homework #6/7 ceni
- Graphs
 - Topological Sort
 - Shortest Paths Algorithms

3/STR/MOT/DEC/1/A Graph Traversals

Breadth-first search

 explore all adjacent nodes, then for each of those nodes explore all adjacent nodes

Depth-first search

- explore first child node, then its first child node, etc. until goal node is found or node has no children. Then backtrack, repeat with sibling.
- Both:
 - Work for arbitrary (directed or undirected) graphs
 - Must mark visited vertices so you do not go into an infinite loop!
- Either can be used to determine connectivity:
 - Is there a path between two given vertices?
 - Is the graph (weakly) connected?
- Which one:
 - Uses a queue? BFS
 - Uses a stack? **DF**
 - Always finds the shortest path (for unweighted graphs)?

BFS

4/EXP/MOT/XPL/1/A The Shortest Path Problem

Given a graph G, edge costs $c_{i,j}$, and vertices s and t in G, find the shortest path from s to t.

For a path $p = v_0 v_1 v_2 \dots v_k$ - unweighted length of path p = k (a.k.a. length)

- weighted length of path $p = \sum_{i=0..k-1} c_{i,i+1}$ (a.k.a cost)

Path length equals path cost when?

5/SOL/MOT/DEF/1/A Single Source Shortest Paths (SSSP)

Given a graph G, edge costs $c_{i,j}$, and vertex s, find the shortest paths from s to all vertices in G.

Is this harder or easier than finding the shortest path from s to t?

6/SOL/MOT/DEF/1/A All Pairs Shortest Paths (APSP)

Given a graph G and edge costs $c_{i,j}$, find the shortest paths between <u>all pairs</u> of vertices in G.

– Is this harder or easier than SSSP?

- Could we use SSSP as a subroutine to solve this?

7/EXP/MOT/DED/1/A

Variations of SSSP

- Weighted vs. unweighted
- Directed vs undirected
- Cyclic vs. acyclic
- Positive weights only vs. negative weights allowed
- Shortest path vs. longest path

— ...

8/STR/APP/DEF/1/A

Applications

- Network routing
- Driving directions
- Cheap flight tickets
- Critical paths in project management (see textbook)

— ...

9/SOL/MOT/DEF/1/A

SSSP: Unweighted Version

Ideas?

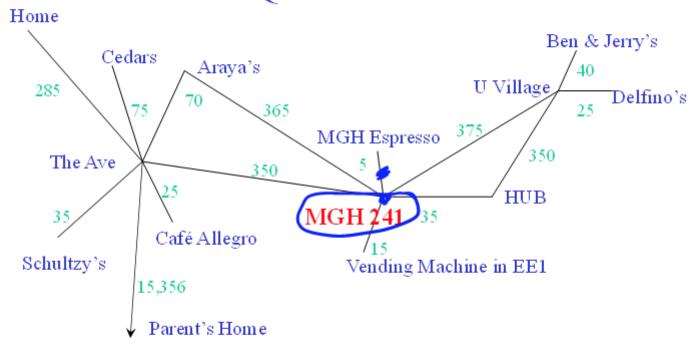

5/21/10

10/EXP/DST/DEO/1/A

```
void Graph::unweighted (Vertex s) {
  Queue q(NUM VERTICES);
  Vertex v, w;
  for all vertices v do {v.dist = INFINITY;}
  s.dist = 0;
  q.enqueue(s);
  while (!q.isEmpty()) {
                                  each edge examined
                                  at most once - if adjacency
    v = q.dequeue();
                                  lists are used
    for each w adjacent to v
       if (w.dist == INFINITY) {
         w.dist = v.dist + 1;
         w.path = v;
         q.enqueue(w);
                                 each vertex enqueued
       }
    }
  }
           total running time: O(
5/21/10
                                                       10
```

11/STR/MOT/DEF/1/A Weighted SSSP: The Quest For Food

Can we calculate shortest distance to all nodes from MGH 241?

12/STR/BKG/FAC/1/A

Edsger Wybe Dijkstra (1930-2002)

- Legendary figure in computer science; was a professor at University of Texas.
- Invented concepts of structured programming, synchronization, and "semaphores" for controlling computer processes.
- Supported teaching programming without computers (pencil and paper)
- 1972 Turing Award
- "In their capacity as a tool, computers will be but a ripple on the surface of our culture. In their capacity as intellectual challenge, they are without precedent in the cultural history of mankind."

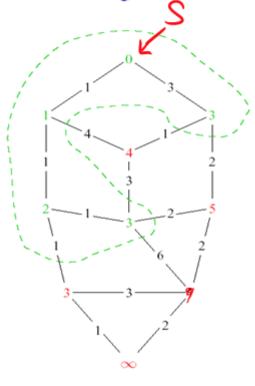

13/STR/ALG/DEC/1/A

Dijkstra's Algorithm for Single Source Shortest Path

- Similar to breadth-first search, but uses a heap instead of a queue:
 - Always select (expand) the vertex that has a lowest-cost path for the start vertex
- Correctly handles the case where the lowest-cost (shortest) path to a vertex is not the one with fewest edges

14/EXP/ALG/DEF/2/A

Dijkstra's Algorithm: Idea

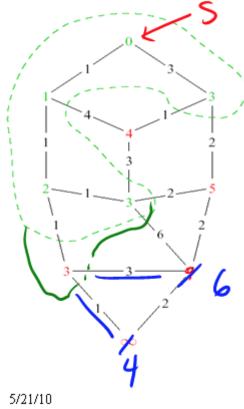

Adapt BFS to handle weighted graphs

Two kinds of vertices:

- Finished or known vertices
 - Shortest distance has been computed
- Unknown vertices
 - Have tentative distance

Dijkstra's Algorithm: Idea

At each step:

- Pick closest unknown
 vertex
- 2) Add it to known vertices
- 3) Update distances

16/EXP/ALG/DEO/1/A

Dijkstra's Algorithm: Pseudocode

Initialize the cost of each node to ∞ Initialize the cost of the source to 0

```
While there are unknown nodes left in the graph

Select an unknown node b with the lowest cost

Mark b as known

For each node a adjacent to b

a's cost = min(a's old cost, b's cost + cost of (b, a))
```

17/EXP/ALG/DEO/1/A

```
void Graph::dijkstra(Vertex s) {
   Vertex v,w;

   Initialize s.dist = 0 and set dist of all other vertices to infinity

   while (there exist unknown vertices, find the one b with the smallest distance)
      b.known = true;

   for each a adjacent to b
      if (!a.known)
        if (b.dist + Cost_ba < a.dist) {
            decrease(a.dist to= b.dist + Cost_ba);
            a.path = b;
      }
   }
}</pre>
```

18/EXP/ALG/XPL/1/A

Important Features

- Once a vertex is made known, the cost of the shortest path to that node is known
- While a vertex is still not known, another shorter path to it might still be found
- The shortest path itself can found by following the backward pointers stored in node.path

5/21/10 19

v6

20/EXP/ALG/DEO/1/A Dijkstra's Alg: Implementation

```
Initialize the cost of each node to ∞
Initialize the cost of the source to 0
While there are unknown nodes left in the graph
Select the unknown node b with the lowest cost
Mark b as known
For each node a adjacent to b
a's cost = min(a's old cost, b's cost + cost of (b, a))
```

Running time?

21/STR/ALG/DEC/1/A

Dijkstra's Algorithm: a Greedy Algorithm

Greedy algorithms always make choices that currently seem the best

- Short-sighted no consideration of long-term or global issues
- Locally optimal does not always mean globally optimal!!

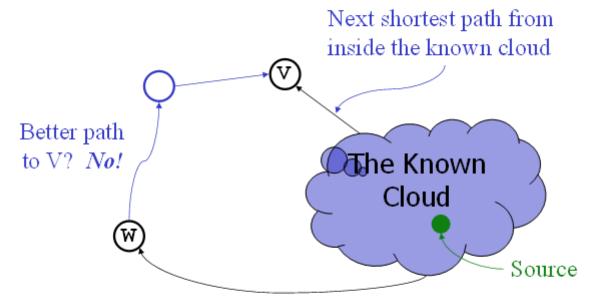

22/EXP/ALG/XPL/1/A

Dijkstra's Algorithm: Summary

- Classic algorithm for solving SSSP in weighted graphs without negative weights
- A greedy algorithm (irrevocably makes decisions without considering future consequences)
- Intuition for correctness:
 - shortest path from source vertex to itself is 0
 - cost of going to adjacent nodes is at most edge weights
 - cheapest of these must be shortest path to that node
 - update paths for new node and continue picking cheapest path

23/STR/ALG/DEC/1/A

Correctness: The Cloud Proof

How does Dijkstra's decide which vertex to add to the Known set next?

- If path to V is shortest, path to W must be at least as long (or else we would have picked W as the next vertex)
- So the path through W to V cannot be any shorter!

 5/21/10

23

24/EXP/ALG/XPL/1/A

Correctness: Inside the Cloud

Prove by induction on # of nodes in the cloud:

Initial cloud is just the source with shortest path 0

Assume: Everything inside the cloud has the correct shortest path

<u>Inductive step</u>: Only when we prove the shortest path to some node v (which is <u>not</u> in the cloud) is correct, we add it to the cloud

When does Dijkstra's algorithm not work?

25/STR/ALG/DEF/1/A

Dijkstra's

At each step:

- 1) Pick closest unknown vertex
- 2) Add it to finished vertices
- Update distances

Dijkstra's Algorithm

VS

BFS

At each step:

- 1) Pick vertex from queue
- 2) Add it to visited vertices
- 3) Update queue with neighbors

Breadth-first Search

26/STR/ALG/DEF/1/A The Trouble with Negative Weight Cycles

What's the shortest path from A to E?

Problem?
